Background. According to the national registries of European countries and epidemiological studies, the prevalence of chronic heart failure (CHF) among adults is 2.0–5.0%, and increases due to age, in people aged over 70 years old it is 10.0–20.0%.

Objective. To find out the specific features of remodeling of the left atrium and change of vasodilation factors in ischemic heart failure with reduced and preserved left ventricular ejection fraction and to establish correlation relationships.

Methods. A full clinical examination of 153 patients with CHF (105 men and 48 women) was conducted to achieve this objective. The surveyed patients underwent clinical examinations; spectrophotometric parameters: quantification of markers of vasodilation, metabolites of monoxide nitrogen — nitrates and nitrites with Gris reagent; content of endothelial nitric oxide synthesise (eNos) in serum — ELISA for the set of Nitric Oxide Synthase 3, Endothelial (NOS3) Human ELISA Kit (Cloud-Clone Corp, USA). Electrocardiographic (ECG) examination was conducted in 12 standard conventional leads on electrocardiograph by the Hungarian production Heart Screen 112 D.

Results. The 1st group of the examined patients with reduced LV eF prevails III (significant) degree LA dilatation in 33 (70.21%) cases, II (moderate) degree of LA dilatation was determined in 14 (29.78%), and I (initial) degree was not defined at all. In the 2nd group of the patients with preserved LV eF mainly the II degree of LA dilatation was determined in 44 (44.51%) cases, and decreased LA dilation in 39 (36.79%) cases (p<0.01), and III degree of LA dilation was defined in 23 (21.69%) cases (p<0.01). In patients with stable coronary heart disease, complicated by heart failure with reduced LV EF and II degree of LA dilatation, eNOS levels in the serum was 449.00±39.91 pg/ml, whereas in patients with stable coronary heart disease, complicated by heart failure with preserved LV EF and II stage of LA dilation — 673.56±50.98 pg/ml (p<0.01). At III stage of LA dilation in patients of the 1st group level eNOS was 344.20±51.98 pg/ml in the patients of the 2nd group — 616.90±36.49 pg/ml (p<0.01). At the same degree and with LA dilation in the patients of the 2nd group eNOS was 750.27±99.85 pg/ml.

Conclusions. The structural and functional changes of the left atrium and changing factors of vasodilation in patients with stable coronary artery disease of II–III functional classes complicated by heart failure of I–III functional classes are studied. It is established that in the examined patients with stable coronary heart disease complicated by heart failure with reduced left ventricular ejection fraction mainly III (significant) degree of dilatation of the left atrium was determined, while in patients with stable coronary heart disease, complicated by heart failure with preserved left ventricular ejection fraction mainly II (moderate) degree of dilatation of the left atrium was determined. In comparison with the results of research among the patients with stable coronary heart disease, complicated by heart failure with reduced left ventricular ejection fraction, and a group of patients with preserved left ventricular ejection fraction, it was determined a significant decrease in eNOS, nitrites, total amount of nitrites and nitrates.

KEY WORDS: heart remodeling factors of vasodilation, heart failure.

Introduction

According to the national registries of European countries and epidemiological studies, prevalence of chronic heart failure (CHF) among adults is 2.0–5.0%, and increases in proportion to age, people aged over 70 years it is from 10.0 to 20.0% [16]. Considering demo-
The criteria for inclusion. Patients with stable coronary artery disease II-III FC followed by CHF II-III FC on informed consent to participate in the study. Exclusion criteria: CHF FC IV by the NYHA; period up to 3 months from the beginning of acute myocardial infarction, or stroke; implanted artificial pacemaker or need of implantation; severe diseases of respiratory system, kidneys, liver with hepatic insufficiency, anaemic state of haemoglobin 90.0 g/dL and below; the formation of malignant disorders and severe neuro-psychiatric disorders.

Among the patients who participated in the study mail prevailed. The average age of patients was 68.80±0.90 years. Hypertension was defined in 132 (86.27%) patients. Systolic blood pressure (BP) was 142.40±5.01 mm Hg, diastolic blood pressure — 88.30±2.95 mmHg.

The examined patients underwent clinical (complaints, case history, physical examination); laboratory tests (general clinical blood and urine tests, blood glucose, bilirubin, cholesterol, β-lipoprotein, creatinine, urea, coagulation parameters); spectrophotometric parameters: quantification of vasodilation markers metabolites of monoxide nitrogen: nitrates and nitrates with Gris reagent; content of endothelial nitric oxide synthase (eNOS) in serum — ELISA for the set of Nitric Oxide Synthase 3, Endothelial (NOS3) Human ELISA Kit (Cloud-Clone Corp, USA). Electrocardiographic (ECG) examination was conducted in 12 standard conventional leads on electrocardiograph Heart Screen 112 D made in Hungary. Statistical analysis was performed with standard statistical package STATISTICA 6.0. For primary analysis of tables and intermediate calculations Microsoft Excel package was used.

Results and Discussion

The decrease in left atrium (LA) dilation degree in patients with stable coronary heart disease complicated by heart failure with reduced and preserved LV EF is presented in Table 1.

In Table 1 the 1st group of the examined patients with reduced LV EF prevails III (significant) degree of LA dilatation in 33 (70.21%) cases, II (moderate) degree of LA dilatation in 14 (29.78%), I (initial) degree is not defined at all. In the 2nd group of patients with preserved LV EF the degree of dilatation II LA was determined in 44 (44.51%) cases, and slightly decreased degree of LA dilatation in 39 (36.79%) cases (p<0.01), III degree of LA dilatation in 23 (21.69%) cases (p<0.01).
Remodeling of myocardium, including hypertrophy and dilation of left ventricle with changes of its geometry and a contraction violation precedes clinical skim CHF manifestations [7]. Thus, remodeling is a harbinger of heard activity decompensation [7, 13]. The features of myocardial remodeling are studied the most in patients after myocardial infarction with heart failure development [7, 8, 14].

These results are consistent with the data that myocardial ischemia may be accompanied by its dysfunction [7].

The study of factors of vasodilation levels and degrees of LA dilatation in patients with stable coronary heart disease complicated by heart failure with reduced and preserved LV EF is presented in Table 2.

In patients with stable coronary heart disease complicated by heart failure with reduced LV EF and II degree of LA dilatation, eNOS levels in the serum is 449.00±39.91 pg/ml, whereas in patients with stable coronary heart disease complicated by heart failure with preserved LV EF and II stage of LA dilatation — 673.56±50.98 pg/ml (p<0.01). At III stage of LA dilatation in patients of group 1 the eNOS level is 344.20±51.98 pg/ml in patients of groups 2 — 616.90±36.49 pg/ml (p<0.01). At the same degree and with LA dilatation in patients of group 2 eNOS is 750.27±99.85 pg/ml. Thus, in the examined patients with the progression of heart failure the endothelial factors decrease, e.g. eNOS.

In the study of levels of metabolites of nitrogen monoxide — nitrates and nitrates in blood serum the following data were obtained: in patients with stable coronary heart disease, complicated by heart failure with reduced LV EF and II and III stage of LA dilatation, the total level of nitrates and nitrites in serum was significantly lower than in patients with stable coronary heart disease, complicated by heart failure with preserved LVEF and II and III stage of LA dilatation (p<0.01).

Among the patients of group 1 with reduced LV EF with the progression of LA dilation degree from II (moderate) stage to III (large) one, eNOS levels in blood serum decreased by 23.34%.

Notes:

* — comparison of patients with stable coronary heart disease complicated by heart failure with reduced LV EF and preserved LV EF and II degree of left atrium dilatation (p=0.01);

* — comparison of patients with stable coronary heart disease complicated by heart failure with reduced LV EF and preserved LV EF and III degree of left atrium dilatation (p<0.01).
Among the patients of group 2 with preserved LV EF with the progression of LA dilatation from I (initial) stage to II one, the level of eNOS in blood serum decreased by 12.89%, and with the progression of the II stage to III one LA dilation reduced by 8.41%.

In the examined patients with stable coronary artery disease complicated by heart failure with reduced left ventricular ejection fraction, the correlation analysis between indicators of linear dimensions of LA and eNOS levels in the blood serum a direct correlation of medium strength ($r=0.38$) ($p<0.01$) was established. Carrying out a similar correlation analysis for patients with stable coronary heart disease complicated by heart failure with preserved LV EF also allowed to establish a direct correlation of weak force ($r=0.21$) ($p<0.01$).

Progressive hypertrophy and dilatation of heart was followed by subsequent first diastolic disruption and then systolic ventricular dysfunction, increased myocardial oxygen demand, changes in subendocardial blood flow, myocardial bioenergy disorders and increased risk of life-threatening ventricular arrhythmias [1].

Recent research proved instrumental and morphological parallels, so we expand on the remodeling of heart as a single clinical and morphological syndrome that is important for making prognosis in patients with coronary heart disease [18].

Conclusions
In patients with stable coronary heart disease complicated by heart failure with reduced left ventricular ejection fraction III (significant) degree of left atrium dilatation was mainly determined, while in patients with stable coronary heart disease complicated by heart failure with preserved left ventricular ejection fraction II (moderate) degree of left atrium dilatation was mainly determined.

In the patients with stable coronary heart disease complicated by heart failure with reduced left ventricular ejection fraction in comparison with the group of patients with preserved left ventricular ejection fraction, the significant reduction of eNOS, nitrites, total of nitrites and nitrates was defined during the study.

The research allowed to establish the direct correlation of medium strength ($r=0.38$) between parameters of linear left atrial size and eNOS levels in blood serum of the patients with stable coronary artery disease complicated by heart failure with reduced left ventricular ejection fraction ($p<0.01$) and the direct correlation of weak force ($r=0.21$) in the examined patients with stable coronary artery disease complicated by heart failure with preserved left ventricular ejection fraction ($p<0.01$).
