OP01-1

The Phenomenon of Fetal Liver Regeneration Activity after Liver Resection

Davit Tophuria, Maia Matoshvili

Human Normal Anatomy, Tbilisi State Medical University, Georgia

Backgrounds: The process of liver regeneration is very complex and is dependent on the etiology and extent of liver damage and the genetic background. Liver regeneration is still not fully understood. The liver is a unique organ, and first in line, the hepatocytes encounter the potential to proliferate during cell mass loss. This phenomenon is tightly controlled and resembles in some way the embryonic co-inhabitant cell lineage of the liver, the embryonic hematopoietic system.

Methodology: The experimental research was conducted on white lab rats. The animals were divided in two groups. First group consists of fetal rats (two weeks old), second group – 5 month age mature female rats. In both of groups was done 25% resection of liver tissue. After 24, 48 and 72 hours was investigated time of maximal activity of DNA, mitochondria synthesis and hepatocytes proliferation.

Results: Laboratory investigations were shown, that after 24 hours in 1-st group was significant increase of mitochondria synthesis. After 48 hours in 1-st group of experimental animals was not changes of hepatocyte size, while in 2-nd group were seen hepatocyte enlargement and temporary increase in numbers of lysosomes, autophagosomes, and micro bodies. There was the different commencement of DNA synthesis and mitosis in the hepatocytes of 1-st with later extension in the hepatocytes of 2-nd group. Thus, the time of maximal activity was indicated in 1-st group much more earlier than in 2-nd group of experimental animals.

Keywords: Liver, Regeneration, Hepatocyte.

OP01-2

ICG-Fluorescence Guided Liver Resection

Kiyoshi Hasegawa, Akinori Miyata, Yoshikuni Kawaguchi, Takeaki Ishizawa, Keigo Tani, Kiyohiko Oomichi, Junichi Kaneko, Junichi Arita, Nobihisa Akamatsu, Ryuji Yoshioka, Yoshihiro Sakamoto, Norihiro Kokudo

Hepato-Biliary-Pancreatic Surgery Division, University of Tokyo, Japan

Backgrounds: Anatomic resection for HCC has been regarded as effective and the standard procedure, however, how to identify a division line in anatomic resection remains a technical problem. Although injection of indigocarmine to the target portal vein is the first choice for the identification, it is difficult to know clear demarcation line in some cases. Another possible choice is staining hepatic segment using indocyanine green (ICG)-fluorescence imaging.

Methods: The procedures, which will be shown in detail using a video clip during a presentation, are summarized, as follows. After hepatic mobilization, mixture of indigocarmine (5 ml) and ICG (0.25 mg) is injected into a portal venous branch corresponding to the hepatic segment to be identified. Fluorescence images of the liver surfaces were obtained using a commercially-available near-infrared light camera system following injection of ICG solution. Then, hepatic parenchyma was transected along a demarcation between fluorescing regions and non-fluorescing lesions. To evaluate the efficacy of this technique, we used both ICG fluorescence imaging and indigo-carmin staining in 30 patients undergoing anatomic segmentectomies for hepatic malignancies between 2012 and 2014.

Results: Outcomes of the indigo-carmin staining technique were classified as ‘effective’ in 17 patients (57%) and ‘fair’ in 13 patients (43%), while identification of hepatic segments by ICG fluorescence imaging was deemed ‘effective’ in all 30 patients (100%).

Conclusion: The ICG fluorescence imaging has become one of the basic techniques for liver surgery.

Keywords: Indocyanine green, Fluorescence, Anatomic resection.

PP2-035**Clinical Benefits of Neoadjuvant Chemoradiotherapy for Adenocarcinoma of the Pancreatic Head: An Observational Study Using Inverse Probability of Treatment Weighting**

Tomonari Asano¹, Tsutomu Fujii¹, Sohei Satoi², Suguru Yamada¹, Kenta Murotani³, Hiroaki Yanagimoto², Mitsuro Kanda¹, So Yamaki², Satoshi Hirooka², Masanori Kon², Yasuhiro Kodera¹

¹Department of Gastroenterological Surgery (Surgery II), Nagoya University Graduate School of Medicine, ²Department of Surgery, Kansai Medical University, ³Division of Biostatistics, Clinical Research Center, Aichi Medical University, Japan

Background: The efficacy of neoadjuvant chemoradiotherapy (NACRT) and subset of pancreatic ductal adenocarcinoma (PDAC) patients who are most likely to benefit from this strategy remain elusive. The aim of this study was to investigate the effects of NACRT in patients with resectable (R) or borderline resectable (BR) adenocarcinoma of the pancreatic head. BR diseases were classified into two groups: lesions involving exclusively the portal vein system (BR-PV) and those abutting the major artery (BR-A).

Methods: A total of 504 patients treated with curative intent for PDAC were analyzed. Patients who underwent upfront surgery and those who underwent NACRT followed by surgery were compared using propensity score-matched and inverse probability of treatment-weighted analyses (UMIN000019719).

Results: No significant differences were noted in the incidences of curative resection among the three categories (R, $n = 273$; BR-PV, $n = 129$; BR-A, $n = 102$). Propensity score-weighted logistic regression analysis revealed that the incidence of pathological lymph node metastasis was significantly reduced in the NACRT group in all three categories, but the incidence of pathologically positive resection margins was reduced by NACRT only for the BR patients. Among the propensity score-matched patients, NACRT rather than upfront surgery significantly prolonged the median survival time of BR-PV patients (28.4 vs. 20.1 months; $P = 0.044$) but not that of R-PDAC patients (28.6 vs. 33.7 months; $P = 0.960$). NACRT prolonged the median survival time of BR-A patients (18.1 vs. 10.0 months; $P = 0.046$), but the results remained unsatisfactory.

Conclusions: These findings suggest that NACRT improves R0 rates and increases the survival of patients with BR-PV adenocarcinoma of the pancreatic head but not that of patients with R-PDAC. NACRT for BR-A patients brought significant downstaging such as reducing pathological lymph node metastasis and positive resection margins, but it is controversial whether surgery influence the improvement of prognosis.

Keywords: Pancreatic ductal adenocarcinoma, Borderline resectable, Neoadjuvant chemoradiotherapy, Upfront surgery, Portal vein.

PP2-036**The Results of Surgical Treatments for Periapillary Malignancies**

Viktoria Petrushenko, Kate Pankiv, Vadim Stoika, Viktor Melnyk

Surgery, Vinnitsa National Medical University, Ukraine

Background: Proximal pancreatectomy is a first choice procedure in a treatment of periapillary malignancies. It can be performed as a duodenopancreatectomy (DP) which could be done as a standard (D1), radical (D2), radical extended (D3) Whipple's procedure, pilorus preserving pancreatic head resection (PPDP) and duodenum preserving pancreatic head resection (DRCP).

Methods: On our department in the period from 2000–2015 we have operated on 206 patients with various periapillary malignancies. Standard Whipple's procedure was done in 72 (35%), radical Whipples procedure in 80 (39%) and PPDP in 54 (26%) patients. No DRCP was done in this series.

Results: R0 resection was achieved in all patients. Definite histological findings revealed: pancreatic head adenocarcinoma 60%, adenocarcinoma of Vater's papilla in 34%, distal common bile duct cholangiocarcinoma 4%, duodenal adenocarcinoma 1% and leiomyosarcoma 1%. Most frequent analyzed and involved lymph nodes were in groups 13, 17, 12, 8, 14, 16.

Conclusion: There were no significant difference in long term survival between three groups of patients (D1, D2, PPDP). Resection can be considered as a palliative or even unnecessary in following terms: involvement of lymph node groups 12 h and 9, and involvement of paraortic and mesenteric lymph nodes.

PP2-037**Clinical Role of Staging Laparoscopy and Risk Factors for Peritoneal Metastasis in Patients with Radiographically Defined Locally Advanced Pancreatic Ductal Adenocarcinoma**

So Yamaki, Sohei Satoi, Hiroaki Yanagimoto, Tomohisa Yamamoto, Hisashi Kosaka, Satoshi Hirooka, Masaya Kotsuka, Hironori Ryota, Youichi Matsui, Masanori Kon

Department of Surgery, Kansai Medical University, Japan

Backgrounds: Staging laparoscopy has been routinely introduced in patients with radiographically defined locally advanced (RD-LA) pancreatic ductal adenocarcinoma (PDAC) for further exploration of minute distant organ metastasis which were not detected by conventional staging modalities since 2007. In this study, we investigated the rate of minute distant organ metastasis and the risk factors for peritoneal metastasis (positive peritoneal washing cytology or peritoneal dissemination).

Methods: According to NCCN criteria, patients with PDAC were categorized as resectable, borderline resectable, unresectable PDAC using MDCT between 2007 and 2015. Staging laparoscopy was performed in 110 patients with RD-LA who were divided into 4 groups according to metastatic site: Group CY (peritoneal fluid or washing cytology positive and without any distant organ metastasis); Group P (peritoneal dissemination without other distant
